## Authors' contributions

This work was carried out in collaboration among all authors. Author KK planned the experiment and lead the research. Authors KK and BRB designed and carried out the research. Author MEH performed the statistical analysis. Authors BRB, JA, MNI and MRI collected the data. Authors BRB, MEH and MA wrote the manuscript. Authors BRB, JA, MNI and MRI managed the literature searches. All authors provided critical feedback and helped in shape the research, analysis and manuscript. All authors read and approved the final manuscript.

Original Research Article

# ABSTRACT

An experiment on effect of organic manure & mulching on the growth and yield of carrot was conducted at the farm of Sher-e-Bangla Agricultural University, Dhaka during the period from November 2017 to February 2018. The research consisted in Randomized Complete Block Design (RCBD) with three replications under a factorial arrangement (of two factors), with Four levels of organic manure, as the factor A and four mulches such as factor B. Organic manure and mulching influenced significantly (p=0.05) all the studied variables. In case of organic manure the maximum plant height (44.55 cm) root length (14.73 cm), root diameter (4.11 cm), root weight (124.50 g), root

\*Corresponding author: E-mail: shawonjess@gmail.com;

yield (24.90 t/ha) and marketable root yield (23.85 ton/ha) were recorded from  $O_2$  (Vermicompost) treatment. In case of mulches, maximum plant height (44.81 cm), root length (15.20 cm), root diameter (3.91 cm), root weight (117.85 g), root yield (23.57 t/ha) and marketable root yield (21.95 t/ha) found in  $M_2$  (Black polythene) treatment. And the combined effect of the highest root yield (29.06 t/ha) was obtained from  $O_2M_2$  (Vermicompost + black polythene) and lowest (13.20 t/ha) from  $O_0M_0$  (control). So, it can be concluded that 10 ton/ha vermicompost with black polythene mulch was the best for carrot cultivation. The highest gross return (Tk. 563200), net return (Tk. 446355) and BCR (4.82) were obtained from the treatment combination from  $O_2M_2$  where the lowest gross return (Tk. 207800), net return (Tk.112755) were obtained from  $O_0M_0$  and lowest BCR (1.67) from  $O_1M_0$ .

Keywords: Daucus carota; growth; mulching; organic manure; yield.

# **1. INTRODUCTION**

Carrot (Daucus carota L.) is one of the most ancient vegetable. It is grown in spring, summer and autumn in temperate countries and during winter in tropical and subtropical countries [1] and extensively cultivated in North and South America, Europe, Asia, North Africa [2]. It belongs to Apiaceae family and said to be originated in Mediterranean region and its cultivation as a crop also began in that region [3]. It has high nutritive value and possible diversified use in making different palatable foods like soups, stews, curries, salad, pickles, halua and jam. It contains appreciable amount of carotene, which can contribute a lot to overcome blindness of children in Bangladesh. The carrot is one of the profitable crops in Bangladesh. The edible part of this crop is characterized by its high beta carotene content, a precursor of vitamin A [4] and acts as an excellent source of iron, calcium, phosphorus, vitamin B, sugar and folic acid. It has been reported that the entire production of carrot was 14075 metric tons under 1415 ha in Bangladesh during 2009-2010 year [5]. An average yield of carrot is about 25 tons/ha in Bangladesh [6] which are comparatively low from major carrot producer countries [7]. It grows successfully in Bangladesh during Rabi season when temperature ranges from 11.17°C to 28.9°C [8] and mid November to early December is the best time for its cultivation to get satisfactory yield [9]. The cultivation of carrot requires an ample supply of plant nutrient. Use of organic manure is essential for its proper growth and development. Organic matter content of Bangladesh soil is below 1% in about 60% cultivable land as compared to an ideal minimum value of 5% organic matter. In the area of continuous cropping, organic matter is supplied to soil through cowdung, compost, poultry manure etc. Several attempts have been made to increase the yield potential of root crops, but

farmers are concerned with the use of inorganic fertilizers which results in decrease fertility of soil, soil health, contents of organic matter and decreases the microbial activity of soil [10]. Vermicompost the is product of the composting process using various species of worms, usually red wigglers, white worms, and other earthworms, to create a mixture of decomposing vegetable or food waste, bedding materials. is regarded ecologically sound biofertilizer and also cost-effective and eco-friendly [11]. Vermicompost is a potential source of readily available nutrients, growth enhancing substances and a number of beneficial microorganisms like N-fixing, P- solubilizing and cellulose decomposing organisms [12,11]. It has been studied that the vermicompost effects on the plant growth, yield and quality of crops considerably. As a result, the seed germination, vigour, flowering and fruiting of plant, tuberization, development of root size colour shelf life and quality are apparently improved [13,14]. On an average Vermicompost contains 1.6% N, 0.7% P, 0.8% K, 0.5% Ca and 0.2% Mg. (Source: Panjab State Council for Science and Technology). In Bangladesh cowdung is used as organic manure. Due to inadequate an knowledge about the merits of organic manure. the farmers habituated extensive use of inorganic fertilizers. On an average, well rotten cowdung contains 0.5% N, 0.2% P<sub>2</sub>O<sub>5</sub> and 0.5% K<sub>2</sub>O [15]. In Bangladesh carrot is grown during winter season when the rainfall is scanty. So irrigation is essential for cultivation. But it increases the cost of cultivation. Under such condition mulching may be useful in reducing irrigation requirement. To serve this purpose water hyacinth, wood ash and black polythene sheets may be used as mulching materials. Mulching is highly effective in checking evaporation loss of soil moisture. Mulching protects the loss of soil moisture by soil evaporation induced by wind and reduces the irrigation requirement [16]. It increases the

efficiency of applied N-fertilizer and irrigation [17]. Different mulches regulate soil moisture and temperature, suppress weeds and improve germination and emergence [18]. In addition, mulches increase microbial activity in the soil [19]. Higher yield and better quality, less infestation of insects diseases, earliness, prolong growing season, higher nutritive value of the produced, improved storability are the advantages of mulching [20]. In some extent, mulches reduce the invasion of insects and diseases [21].

# 2. MATERIALS AND METHODS

# 2.1 Experimental Site

The experiment was conducted at the Horticulture Farm of the Sher-e-Bangla Agricultural University, Dhaka during November, 2017 to February, 2018. Laboratory works were done at Horticulture Laboratory in Sher-e-Bangla Agricultural University, Dhaka-1207. Location of the site is 23°74' N latitude and 90°35' E longitude with an elevation of 8 meter from sea level in Agro-ecological zone of "Madhupur Tract" (AEZ-28). The soil was sandy loam in texture having pH 5.46- 5.62 and EC 0.60 dS/m.

# 2.2 Experiment Frame Work

The research was consisted of two factors: Factor A: four level of organic manure as  $O_0 =$ No organic manure, O<sub>1</sub>= Cowdung (20 ton/ha),  $O_2$  = Vermicompost (10 ton/ha),  $O_3$  = Cowdung(10 ton/ ha) + Vermicompost (5 ton/ha). Factor B: Different type of mulches  $M_0 = No$ mulch,  $M_1$  = Water hyacinth  $M_2$  =Black polythene  $M_3$  = Wood ash. The two factor experiment was laid out in a Factorial Completely Randomised Block Design (FCRBD) with three replications. The whole experimental area was 24.5 m x 5.75 m which was divided into three blocks. Each block was again divided into 16 plots and hence there were 48 (16 x 3) unit plots. The treatments were assigned randomly in each block separately. The size of unit plot was 1.25 m x 1.0 m. The distance between two adjacent blocks and plots were 1.0 m and 0.5 m respectively.

# 2.3 Manure and Fertilizer Application

The sources of applied N,  $P_2O_5$ ,  $K_2O$  were as cowdung, vermicompost. The entire amounts of cowdung and vermicompost were applied during the final land preparation as per treatments.

# 2.4 Application of Mulching

Before sowing of seeds mulching was done with water hyacinth, wood ash and black polythene as per treatments. Fresh water hyacinth as chopped into small pieces (8-10 cm) and dry then placed over the plots with a thickness of 12 cm approximately. Black polythene sheet with small holes at plant distance was spread over the plots accordingly so that the seedlings could emerge easily through the holes.

# 2.5 Economic Analysis

In computing economics, the varying levels of organic manure and different types of mulches were taken into consideration apart from other costs common to all the treatments as per package of practices. The benefit cost ratio (BCR) was calculated as follows:

BCR = Gross return per hectare (Tk.) ÷ Cost of production per hectare (Tk.)

# 2.6 Statistical Analysis

The recorded data on different growth and yield parameters were calculated for statistical analysis. Analyses of variances (ANOVA) for most of the characters under consideration were performed with the help of MSTAT program. Treatment means were separated by Duncane's Multiple Range Test (DMRT) at 5% level of significance for interpretation of the results.

# **3. RESULTS AND DISCUSSION**

# 3.1 Plant Height

Plant height of carrot has measured at 30, 50, 70 days after sowing and at harvest. Fig. 1, Showing that the maximum plant height was found (44.55cm) from the  $O_2$  (Vermicompost 10 ton/ha) treatment at harvest, while the minimum height was observed (38.99cm) from  $O_0$  (control) treatment. Rashid and Shakur, [22] reported similar results in plant height. Among the mulches materials treatment  $M_2$  (black polythene) mulch produced the tallest plant (18.88 cm, 33.81 cm, 41.01 cm and 44.81 cm) at 30, 50, 70 DAS and at harvest respectively and followed by the  $M_1$  (Water hyacinth) mulch at the same DAS. The shortest plant was observed for the treatment  $M_0$  (control) (Fig. 2).

The combined effect of organic manure and mulching was found significantly influenced in

terms of plant height of carrot (Table 1). The maximum plant height (23.16 cm, 36.37 cm, 42.77 cm and 48.13 cm) was recorded from  $O_2M_2$  (Vermicompost, 10 ton/ha + black polythene mulch) treatment at 30, 50, 70 DAS and at harvest respectively. On the other hand, the minimum plant height (12.00 cm, 17.22 cm, 30.93 cm and 35.43 cm) was found in plants

of control plot  $O_0M_0$  (No organic + no mulch) treatment at 30, 50, 70 DAS and at harvest respectively. Rashid and Shakur, [22] reported that combined application of 6 ton/ha vermicompost with water hyacinth mulch in carrot was the best for obtaining plant height, number of leaves, root length, root fresh weight and highest marketable yield.

Table 1. Combined effect of organic manure and mulching on plant height at different days of
carrot

Treatments		Plant he	eight (cm)	
	30 DAS	50 DAS	70 DAS	Harvest

#### 3.2 Number of Leaves per Plant

The maximum number of leaves per plant (5.58, 10.48 and 11.72) was recorded from  $O_2$  (Vermicompost, 10 ton/ha) treatment at 50, 70 DAS and at harvest respectively. The minimum leaf number (4.36, 8.25and 10.24) was found from  $O_0$  (control) treatment respectively for same DAS (Fig. 3). Azarme et al. [23] state that the addition of vermicompost at ratio of 15 ton/ha, significantly increased plant growth and yield compared to control.

At 50, 70 DAS and at harvest, the maximum number of leaves per plant (5.56, 10.55 and 12.08) was obtained from  $M_2$  (Black polythene) treatment while the minimum number of leaves per plant (4.55, 8.15 and 10.02) at the same DAS was found from  $M_0$  (No mulch) treatment (Fig. 4). Jaysawal et al. [24] reported that the treatment

black polythene mulch was best among the various mulch treatments and recorded maximum plant height, number of leaves per plant, leaf fresh weight, leaf dry weight, root weight, root length, root diameter and total root yield of carrot.

The combined effect of different organic manure and mulch materials showed significant differences due to their application on number of leaves per plant of carrot at 50, 70 DAS and at harvest (Table-2). The maximum number of leaves per plant At 50, 70 DAS and at harvest was recorded 6.50, 11.77 and 13.00 respectively treatment combination from  $O_2M_2$ (Vermicompost, 10 ton/ha + black polythene) while the minimum number of leaves per plant at 50. 70 DAS and at harvest were 3.73. 7.06 and 9.16, respectively from  $O_0M_0$  (No organic manure + no mulch).

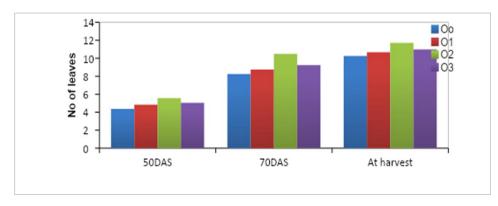

Fig. 3. Effect of different organic manure on no. of leaves per plant at different days after sowing

 $[O_0 = No \text{ organic manure, } O_1 = Cowdung (20 ton/ha), O_2 = Vermicompost (10 ton/ha), O_3 = Cowdung (10 ton/ha) + Vermicompost (5 ton/ha)]$

# 3.3 Root Length (cm)

The longest root length 14.73 cm was recorded from  $O_2$  (Vermicompost (10 ton/ha) treatment while the shortest root length 11.91 cm was observed from control plot (Table 3). This finding is an agreement with the result of Schuch et al., [25], they reported that the root length of carrot varied with different amount of manure application. Root length differed significantly due to the different mulch application. Maximum root length (15.21 cm) was recorded at treatment  $M_2$  (Black polythene) and it was significantly different than other treatments. The minimum root length (11.96 cm) was found at  $M_0$  (No mulch) (Table 5). This result is in accordance with the findings of Rahman et al. [26]. The combined effect of organic manures and mulches showed significant variation on root length of carrot (Table 7). The longest root 17.00 cm was observed from the treatment combination of  $O_2M_2$  (Vermicompost, 10 ton/ha + black polythene). The shortest root length (10.50 cm) was recorded from control  $O_0M_0$  (No organic manure + no mulch) treatment.

Organic manure	Root length (cm)	Root diameter (cm)	Root weight per plant (g)	Root weight per plot (kg)

CV (%)	11.45	12.62	12.43	10.27
LSD (0.05)	0.78	0.22	4.37	0.18

#### 3.4 Root Diameter (cm)

Diameter of root was significantly influenced by the application of different level of organic manure (Table 3). The maximum diameter of root (4.12 cm) was recorded from O<sub>2</sub> (Vermicompost, 10 ton/ha) treatment and it was significantly different than other organic manure treatments. On the other hand, the minimum root diameter (3.14 cm) was observed from O<sub>0</sub> treatment (control). Root diameter was also significantly varied due to the use of different mulching materials in carrot (Table 5). The highest root diameter (3.92 cm) was obtained at the mulches treatment M<sub>2</sub> (Black polythene). The lowest root diameter of root (3.15 cm) was obtained at the treatment of  $M_0$  (No mulch). The maximum diameter of root (4.50 cm) was observed from the treatment combination of  $O_2M_2$ (Vermicompost, 10 ton/ha + black polythene), The minimum diameter of root (2.43 cm) was recorded from control  $O_0M_0$  (No organic manure + no mulch) treatment (Table 7).

## 3.5 Root Weight per Plant (g)

A significant variation was observed on root weight per plant due to use of different organic manures (Table 3). The maximum root weight per plant 124.50 g was recorded from O<sub>2</sub> (Vermicompost, 10 ton/ha) treatment. While the minimum root weight (47.58 g) was recorded from control plots. Lang [27] found that organic manures increased the yield of carrot (10%-20%) compared with control. Different mulches materials showed significant variation for root weight per plant 0f carrot (Table 5). The highest root weight per plant (117.85 g) was found from M<sub>2</sub> (Black polythene). The lowest root weight per plant (92.23 g) was recorded from control treatment. The maximum root weight per plant (82.53 g) was observed from treatment combination of O<sub>2</sub>M<sub>2</sub> (Vermicompost, 10 ton/ha + black polythene) treatment. The minimum root weight per plant (35.73 g) was recorded from control plot O<sub>0</sub>M<sub>0</sub> (No organic manure+ no mulch) (Table 7). Hasan et al. [28] reported that combindly application of vermicompost (6 ton/ha) and water hyacinth mulching gave the highest marketable (27.89 ton/ha) and the gross yield (29.48 ton/ha) of carrot.

# 3.6 Root Yield per Plot (kg)

The maximum root weight per plot 3.11 kg was recorded from O<sub>2</sub> (Vermicompost, 10 ton/ha) treatment. While the minimum root weight (2.13kg) from control plots (Table 3). Different mulch materials showed significant variation for root weight per plot of carrot (Table 5). The highest root weight per plot (2.95 kg) was found from M<sub>2</sub> (Black polythene) treatment. The lowest root weight per plot (2.31 kg) was recorded from control. The combined effect of organic manures and mulch materials was found significant variation was observed on root weight per plot (Table 7). The maximum root weight per plot (3.63 kg) was observed from treatment combination of O<sub>2</sub>M<sub>2</sub> (Vermicompost, 10 ton/ha + black polythene). The minimum root weight per plot (1.65 kg) was recorded from control plot  $O_0M_0$  (No organic manure + no mulch).

# 3.7 Yield per Ha (ton)

The root yield (24.90 ton/ha) recorded maximum from O<sub>2</sub> (Vermicompost, 10 ton/ha) treatment. The minimum root yield (17.00 ton/ha) was obtained from control O<sub>0</sub> (No organic manure) treatment (Table 4). The highest root yield (23.57 ton/ha) was recorded from M<sub>2</sub> (Black polythene) treatment, while the lowest (18.45 ton /ha) was obtained from the control (Table 6). The combined effect of organic manure and mulches was significantly varied on root yield (Table 8). However, the maximum root yield (29.07 ton/ha) was obtained from the treatment combination of O<sub>2</sub>M<sub>2</sub> (Vermicompost, 10 ton/ha + black polythene) which was statistically significant different from the other treatments; whereas the minimum yield (13.20 ton/ha) was recorded from control plot O<sub>0</sub>M<sub>0</sub> (No organic manure + no mulch).

# 3.8 Marketable Yield (ton/ha)

The marketable root yield (23.85 ton/ha) recorded maximum from  $O_2$  (Vermicompost, 10 ton/ha) treatment. The minimum root yield (13.82 ton/ha) was obtained from control  $O_0$  (No organic manure) treatment (Table 4). The highest marketable yield per ha (21.95 ton) was recorded from  $M_2$  (Black polythene) treatment, while the lowest (15.63 ton/ha) was obtained from the control (Table 6).

The combined effect of organic manures and mulches was significantly varied on Marketable yield per ha (Table 8). However, the maximum Marketable root yield per ha (28.16 ton) was obtained from the treatment combination of  $O_2M_2$  (Vermicompost, 10 ton/ha + black polythene) which was statistically significant different from the other treatments; whereas the minimum yield (10.39 ton) was recorded from control plot  $O_0M_0$  (No organic manure + no mulch).

# 3.9 Dry Matter Percentage of Root (%)

The maximum dry matter of root per plant (16.06N%) was recorded from  $O_2$  (Vermicompost, 10 ton/ha) treatment while the minimum (12.16%) from control plots (Table 4). Root dry weight was markedly increased and achieved maximum (15.46%) values in treatment of M<sub>2</sub> (Black polythene) treatment. The lowest root dry weight (13.36%) was observed in control (Table 6).

A significant effect of organic manures and mulches combination on root dry weight was found (Table 8). The highest values of root dry weight (17.78% were recorded due to  $O_2M_2$  (Vermicompost, 10 ton/ha + black polythene) treatment. On opposition to, the lowest ones (10.90%) were proceeded from combination  $O_0M_0$  (No organic manure + no mulch).

Organic manure	Yield (ton/ha)	Marketable yield(ton/ha)	Root dry matter(%)
O <sub>0</sub>	18.45	15.63	12.62
O <sub>1</sub>	21.71	19.24	13.87
O <sub>2</sub>	23.57	21.95	15.46

# 4. CONCLUSION

Based on the results of the present study, it may be concluded that the efficient production of carrot is increased by the judicial application of organic manure with black polythene. The experimental result revealed that the organic manure vermicompost (10 ton/ha) gave the highest yield. Mulching materials such as black polythene may be used for higher yield of carrot. Application of Vermicompost (10 ton/ha) with black polythene mulch is one of the most effective management practices to improve soil productivity. Thus, considering crop productivity, economic return and maintaining soil fertility, the combined application of vermicompost (10 ton/ha) with black polythene mulch may be recommended to farmers for cost-effective carrot production with affecting the soil health.
